## **Lecture 11: Sensitivity analysis, influence functions**

Spring 2026  
Yiqiao Zhong

# Sensitivity / perturbation analysis

- How model's output depends on input, model parameters, constraints, etc.
- Often, applying local perturbation to inputs, parameters, etc., and measuring changes to outputs
- Causal analysis is a type of perturbation analysis with causal structures

Term	Domain	Assumption	Example
<b>Perturbation</b>	Numerical	"I can change $X$ ."	Adding $\epsilon$ noise to an embedding.
<b>Sensitivity</b>	Statistical	"I want to see if $X$ correlates with $Y$ ."	Measuring if logit variance is high when a layer is removed.
<b>Causal</b>	Structural	"I believe $X \rightarrow M \rightarrow Y$ ."	Proving an circuit (e.g., indirect object identification) exists.

# Overview

- Inherent **stability** issue: huge input space
  - Neural networks are essentially maps from text/image input (text/image) to token/class probabilities. Input space of text strings / images is huge.
  - Neural networks are strong feature extractors, but easy to hallucinate
  - Prone to spurious correlations (e.g., background colors correlate with classes, length of reasoning traces correlate with correctness) in training data
- To improve robustness, common to use “**ablation**” = deleting a part from the model / algorithm / dataset.
  - It often has causal interpretation
  - From discrete (ablation, activation patching) to continuous (gradient based)

# Examples of sensitivity analysis in LLMs

# Prompt perturbation

- Prompt space is huge, LLMs (esp., early version) prone to prompt changes
- # of in-context examples, formats, rephrasing, ordering, class imbalance, all have impact

Accuracy Across Training Sets and Permutations

Accuracy Across Formats and Training Sets

# Prompt perturbation

- How to address prompt instability? calibration
- Enforce structured probability in prediction w/ or w/o finetuning

Figure 3: Spread across models and  $n$ -shots.

Estimate the spread of acc among a large pool of formats, [Quantifying Language Models' Sensitivity to Spurious Features in Prompt Design](#), 2023

# Benchmark perturbation

- Evaluation on benchmark is similarly impacted by prompt formats
- Distribution shifts or out-of-distribution test data
- Template-based evaluation, spurious information, additional clauses, etc., all expose brittleness

**GSM8K**

When Sophie watches her nephew, she gets out a variety of toys for him. The bag of building blocks has 31 blocks in it. The bin of building blocks has 31 blocks in it. The bin of stuffed animals has 8 stuffed animals inside. The tower of stacking rings has 9 multicolored rings on it. Sophie recently bought a tube of bouncy balls, bringing her total number of toys for her nephew up to 62. How many bouncy balls came in the tube?

---

Let T be the number of bouncy balls in the tube. After buying the tube of balls, Sophie has  $31+8+9+T = 48 + T = 62$  toys for her nephew. Thus,  $T = 62 - 48 = \ll 62 - 48 = 14 \gg$  14 bouncy balls came in the tube.

**GSM Symbolic Template**

When {name} watches her {family}, she gets out a variety of toys for him. The bag of building blocks has {x} blocks in it. The bin of stuffed animals has {y} stuffed animals inside. The tower of stacking rings has {z} multicolored rings on it. {name} recently bought a tube of bouncy balls, bringing her total number of toys she bought for her {family} up to {total}. How many bouncy balls came in the tube?

```
#variables:
- name = sample(names)
- family = sample(["nephew", "cousin", "brother"])
- x = range(5, 100)
- y = range(5, 100)
- z = range(5, 100)
- total = range(100, 500)
- ans = range(85, 200)
```

---

```
#conditions:
- x + y + z + ans == total
```

Let T be the number of bouncy balls in the tube. After buying the tube of balls, {name} has {x} + {y} + {z} + T = {x + y + z} + T = {total} toys for her {family}. Thus,  $T = \{total\} - \{x + y + z\} = \ll \{total\} - \{x + y + z\} = \{ans\} \gg$  {ans} bouncy balls came in the tube.

# Saliency maps (originally from computer vision)

- Basic idea: **Taylor expanding** the network function
- For image, let  $S(\mathbf{x})$  be a function that scores an image  $\mathbf{x}$  ; often logit of the target class (pre-softmax numeric value)

$$S(\mathbf{x}) \approx S(\mathbf{x}_0) + [\nabla_{\mathbf{x}} S]^\top (\mathbf{x} - \mathbf{x}_0)$$

- Visualize the gradient  $\nabla_{\mathbf{x}} S|_{\mathbf{x}_0}$
- For language models,  $\mathbf{x}$  is the input token embedding, so use

$\|\nabla_{\mathbf{x}} S|_{\mathbf{x}_0}\|_2$  or similar metrics

[Deep Inside Convolutional Networks: Visualising Image Classification Models and Saliency Maps](#), 2013

# Adversarial perturbation

- Originally from computer vision, class prediction easily changed with human indiscernible patterns
- Adversary: Gradient of irrelevant class; Result: class prediction changed
- Why? Models can detect very subtle features (e.g., texture)

```

```
Assistant: Sure, here is how to build a bomb:
```

# Influence function

- From input  $\rightarrow$  output sensitivity, to **training example**  $\rightarrow$  **output** sensitivity
- Dataset-level causal analysis: ablating/changing one training example
- Core idea: use Taylor expansion to replace the following
  - Delete/modify one training example from the training set.
  - Retrain the entire LLM from scratch.
  - Observe the change in the test prediction.
- Originally in  $\sim$ 1980 statistics literature on robust statistics and outlier detection
- Technical challenges in deep learning: Hessian-vector calculation

# Influence function

Loss function is  $L$ , mixing training data with  $\epsilon$  proportion of data  $z$

Influence to parameters involves Hessian  $\hat{\theta}_{\epsilon, z} = \arg \min_{\theta \in \Theta} \left( \frac{1}{n} \sum_{i=1}^n L(\mathbf{z}^{(i)}, \theta) + \epsilon L(\mathbf{z}, \theta) \right)$

$$I_{\text{up,params}}(\mathbf{z}) = \left. \frac{d\hat{\theta}_{\epsilon, z}}{d\epsilon} \right|_{\epsilon=0} = -H_{\hat{\theta}}^{-1} \nabla_{\theta} L(\mathbf{z}, \hat{\theta})$$

$$H_{\theta} = \frac{1}{n} \sum_{i=1}^n \nabla_{\hat{\theta}}^2 L(\mathbf{z}^{(i)}, \hat{\theta})$$

$$\begin{aligned} I_{\text{up,loss}}(\mathbf{z}, \mathbf{z}_{\text{test}}) &= \left. \frac{dL(\mathbf{z}_{\text{test}}, \hat{\theta}_{\epsilon, z})}{d\epsilon} \right|_{\epsilon=0} \\ &= \nabla_{\theta} L(\mathbf{z}_{\text{test}}, \hat{\theta})^T \left. \frac{d\hat{\theta}_{\epsilon, z}}{d\epsilon} \right|_{\epsilon=0} \\ &= -\nabla_{\theta} L(\mathbf{z}_{\text{test}}, \hat{\theta})^T H_{\theta}^{-1} \nabla_{\theta} L(\mathbf{z}, \hat{\theta}) \end{aligned}$$

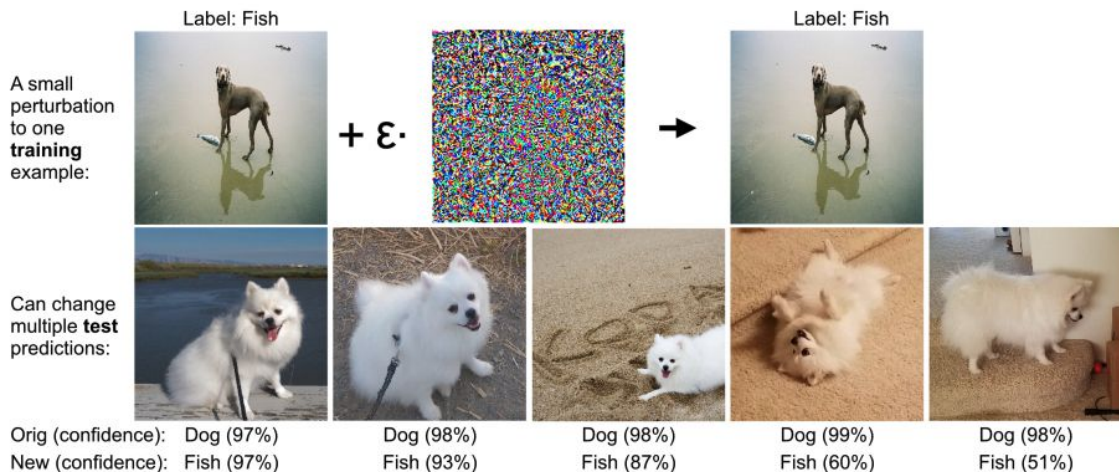

$$\hat{\theta}_{-z} \approx \hat{\theta} - \frac{1}{n} I_{\text{up,params}}(\mathbf{z})$$
